GHAPTER

## * INTRODUCTION

The motion of a particle along a straight line is called rectilinear motion Let the particle start from O along a line. We take line along x -axis. Let after time ' t ', particle be at a point P at a distance ' $x$ ' from O .

Let $\vec{r}$ be the position vector of the point $P$ w.r.t origin $O$. Then

$$
\overrightarrow{\mathrm{r}}=\overline{\mathrm{OP}}=x \hat{\mathrm{i}}
$$

Now $\overrightarrow{\mathrm{v}}=\frac{\mathrm{d} \overrightarrow{\mathrm{r}}}{\mathrm{dt}}=\frac{\mathrm{dx}}{\mathrm{dt}} \hat{\mathrm{i}}$ and $\overrightarrow{\mathrm{a}}=\frac{\mathrm{d} \overrightarrow{\mathrm{v}}}{\mathrm{dt}}=\frac{\mathrm{d}^{2} \mathrm{x}}{\mathrm{dt}^{2}} \hat{i}$
Let $\quad|\vec{v}|=v$ and $|\vec{a}|=a$
Then $v=\frac{d x}{d t} \quad$ and $\quad a=\frac{d^{2} x}{d t^{2}}$
Also $\mathrm{a}=\frac{\mathrm{dv}}{\mathrm{dt}}=\frac{\mathrm{dv}}{\mathrm{dx}} \cdot \frac{\mathrm{dx}}{\mathrm{dt}}$

$$
=\frac{\mathrm{dv}}{\mathrm{dx}} \cdot \mathrm{v}
$$

$\Rightarrow \quad \mathrm{a}=\mathrm{v} \cdot \frac{\mathrm{d} \cdot \frac{\mathrm{dx}}{\mathrm{dx}} .}{}$

## * MOTION WITH CONSTANT ACCELERATION

Let the particle start from O with velocity u at time $\mathrm{t}=0$ with constant acceleration.. Let after time ' $t$ ' particle be at a point $P$ at a distance ' $x$ ' from $O$. Then

$$
\mathrm{a}=\frac{\mathrm{dv}}{\mathrm{dt}} \Rightarrow \mathrm{adt}=\mathrm{dv}
$$

On integrating we get

$$
\begin{equation*}
\mathrm{v}=\mathrm{at}+\mathrm{A} \tag{i}
\end{equation*}
$$

Where A is constant of acceleration.

At $\mathrm{t}=0, \mathrm{v}=\mathrm{u}$
Using this in (i), we get

$$
A=v
$$

Using value of $A$ in (i), we get

$$
\begin{equation*}
\mathbf{v}=\mathbf{u}+\mathbf{a t} \tag{ii}
\end{equation*}
$$

Which is $1^{\text {st }}$ equation of motion.
As we know that

$$
\begin{aligned}
& \mathrm{v}=\frac{\mathrm{dx}}{\mathrm{dt}} \\
\Rightarrow \quad & \frac{\mathrm{dx}}{\mathrm{dt}}=\mathrm{u}+\mathrm{at} \quad \mathrm{By}(\mathrm{ii}) \\
\Rightarrow \quad & \mathrm{dx}=(\mathrm{u}+\mathrm{at}) \mathrm{dt}
\end{aligned}
$$

On integrating we get

$$
\begin{equation*}
x=u t+\frac{1}{2} a t^{2}+B \tag{iii}
\end{equation*}
$$

$\qquad$
At $\mathrm{t}=0, \mathrm{x}=0$
Using this in (ii), we get $\mathrm{B}=0$
Using value of B in (ii), we get

$$
x=u t+\frac{1}{2} a^{2}
$$

Which is $2^{\text {nd }}$ equation of motion.
As $a=v \cdot \frac{d v}{d x} \Rightarrow a \cdot d x=v \cdot d v$
On integrating, we get

$$
a x+C=\frac{v^{2}}{2}
$$

At $\mathrm{t}=0, \mathrm{x}=0, \overrightarrow{2}=\mathrm{u}$
Using these values in(v), we get

$$
\mathrm{C}=\frac{\mathrm{u}^{2}}{2}
$$

Using value of C in (v), we get

$$
\begin{aligned}
& \mathrm{ax}+\frac{\mathrm{u}^{2}}{2}=\frac{\mathrm{v}^{2}}{2} \Rightarrow \quad 2 \mathrm{ax}+\mathrm{u}^{2}=\mathrm{v}^{2} \\
\Rightarrow \quad & \mathbf{2 a x}=\mathbf{v}^{\mathbf{2}}-\mathbf{u}^{\mathbf{2}}
\end{aligned}
$$

## Which is $3^{\text {rd }}$ equation of motion.

If a particle is moving with constant retardation then $\mathrm{a}=-\mathrm{a}$

## * DISTANGE TRAVELLED IN NTH SECOND

Let $\mathrm{x}_{1}$ and $\mathrm{x}_{2}$ be the distances traveled in n and $\mathrm{n}-1$ seconds respectively. Then by $2^{\text {nd }}$ equation of motion we have

$$
\begin{aligned}
& x_{1}=u n+\frac{1}{2} \mathrm{an}^{2} \\
& \mathrm{x}_{2}=\mathrm{u}(\mathrm{n}-1)+\frac{1}{2} \mathrm{a}(\mathrm{n}-1)^{2}
\end{aligned}
$$

and
Distance traveled in $\boldsymbol{n}^{\text {th }}$ second $=\mathrm{x}_{1}-\mathrm{x}_{2}$

$$
\begin{aligned}
& =u n+\frac{1}{2}{a n^{2}-u(n-1)-\frac{1}{2} a(n-1)^{2}}^{=u n+\frac{1}{2} a n^{2}-u n+u-\frac{1}{2} a\left(n^{2}-2 n+1\right)} \\
& =\frac{1}{2} a n^{2}+u-\frac{1}{2} a n^{2}+\frac{1}{2} a(2 n-1) \\
& =u+\frac{1}{2} a(2 n-1)
\end{aligned}
$$

## * QUESTION 1

A particle moving in a straight line starts from rest and is accelerated uniformly to attain a velocity 60 miles per hours in 4 seconds. Finds the acceleration of motion and distance travelled by the particle in the last three seconds.

## SOLUTION

Given that
Initial velocity $=u=0$
Time $=\mathrm{t}=4 \mathrm{sec}$
Final velocity $=\mathrm{v}=60 \mathrm{miles} / \mathrm{h}$

$$
=\frac{60 \times 1760 \times 3}{3600}=88 \mathrm{ft} / \mathrm{sec}
$$

We know that

$$
\begin{aligned}
\mathrm{v} & =\mathrm{u}+\mathrm{at} \\
\Rightarrow \quad \mathrm{a} & =\frac{\mathrm{v}-\mathrm{u}}{\mathrm{t}}=\frac{88-0}{4}=22 \mathrm{ft} / \mathrm{sec}^{2}
\end{aligned}
$$

Now
$\mathrm{x}_{1}=$ Distance covered in $1^{\text {st }}$ second

$$
\begin{aligned}
& =\mathrm{ut}+\frac{1}{2} \mathrm{at}^{2} \\
& =0+\frac{1}{2}(22)(1)^{2}=11 \mathrm{ft}
\end{aligned}
$$

$\mathrm{x}_{2}=$ Distance covered in 4 seconds

$$
\begin{aligned}
& =\mathrm{ut}+\frac{1}{2} \mathrm{at} \mathrm{t}^{2} \\
& =0+\frac{1}{2}(22)(4)^{2}=176 \mathrm{ft}
\end{aligned}
$$

Distance covered in last 3 seconds $=x_{2}-x_{1}$

$$
=176-11=165 \mathrm{ft} .
$$

## * QUESTION 2

Find the distance travelled and velocity attained by a particle moving on a straight line at any timre $t$. If it starts from rest at $t=0$ and subject to an acceleration $\mathbf{t}^{2}+\sin t+\mathbf{e}^{t}$

## SOLUTION

Given that

$$
\begin{aligned}
& \mathrm{a}=\mathrm{t}^{2}+\sin \mathrm{t}+\mathrm{e}^{\mathrm{t}} \\
\Rightarrow \quad & \frac{\mathrm{~d}^{2} \mathrm{x}}{\mathrm{dt}^{2}}=\mathrm{t}^{2}+\sin \mathrm{t}+\mathrm{e}^{\mathrm{t}}
\end{aligned}
$$

On integrating, we get

$$
\frac{\mathrm{dx}}{\mathrm{dt}}=\frac{\mathrm{t}^{3}}{3}-\cos \mathrm{t}+\mathrm{e}^{\mathrm{t}}+\mathrm{A}
$$

Where A is constant of integration
When $\mathrm{t}=0$ then $\frac{\mathrm{dx}}{\mathrm{dt}}=0$
$\Rightarrow \mathrm{A}=0$
Hence velocity is:

$$
\frac{\mathrm{dx}}{\mathrm{dt}}=\frac{\mathrm{t}^{3}}{3} \cos t+\mathrm{e}^{\mathrm{t}}
$$

On integrating again, we get

$$
x=\frac{\mathrm{t}^{4}}{12}-\sin \mathrm{t}+\mathrm{e}^{\mathrm{t}}+\mathrm{B}
$$

Where $B$ is constant of integration
When $\mathrm{t}=0$ then $\mathrm{x}=0$

$$
\Rightarrow \quad \mathrm{B}=-1
$$

Hence the distance travelled is given by

$$
x=\frac{t^{4}}{12}-\sin t+e^{t}-1
$$

## * QUESTION 3

Discuss the motion of a particle moving in a straight line if it starts from rest at $t=0$ and its acceleration is equal to (i) $\mathbf{t}^{\mathbf{n}}$ (ii) acost +bsint $\quad$ (iii) $-\mathbf{n}^{2} \mathbf{x}$

## SOLUTION

(i)

Given that
$a=t^{n}$

$\frac{\mathrm{~d}^{2} \mathrm{x}}{\mathrm{dt}^{2}}=\mathrm{t}^{\mathrm{n}}$
On integrating, we get

$$
\frac{\mathrm{dx}}{\mathrm{dt}}=\frac{\mathrm{t}^{\mathrm{n}+1}}{\mathrm{n}+1}+\mathrm{A}
$$

Where A is constant of integration
When $\mathrm{t}=0$ then $\frac{\mathrm{dx}}{\mathrm{dt}}=0$
$\Rightarrow \mathrm{A}=0$
Hence velocity is:

$$
\frac{\mathrm{dx}}{\mathrm{dt}}=\frac{\mathrm{t}^{\mathrm{n}+1}}{\mathrm{n}+1}
$$

On integrating again, we get

$$
\mathrm{x}=\frac{\mathrm{t}^{\mathrm{n}+2}}{(\mathrm{n}+1)(\mathrm{n}+2)}+\mathrm{B}
$$

Where $B$ is constant of integration
When $\mathrm{t}=0$ then $\mathrm{x}=0$
$\Rightarrow \quad \mathrm{B}=0$
Hence the distance travelled is given by

$$
x=\frac{t^{n+2}}{(n+1)(n+2)}
$$

(ii)

Given that

$$
\begin{aligned}
& \mathrm{a}=\mathrm{a} \operatorname{cost}+\mathrm{b} \operatorname{sint} \\
\Rightarrow \quad & \frac{\mathrm{~d}^{2} \mathrm{x}}{\mathrm{dt}^{2}}=\mathrm{acost}+\mathrm{b} \operatorname{sint}
\end{aligned}
$$

On integrating, we get

$$
\frac{\mathrm{dx}}{\mathrm{dt}}=\mathrm{a} \sin \mathrm{t}-\mathrm{b} \cos \mathrm{t}+\mathrm{A}
$$

Where A is constant of integration
When $t=0$ then $\frac{d x}{d t}=0$
$\Rightarrow \mathrm{A}=\mathrm{b}$
Hence velocity is

$$
\frac{\mathrm{dx}}{\mathrm{dt}}=\mathrm{asint}-\mathrm{b} \operatorname{cost}+\mathrm{b}
$$

On integrating again, we get

$$
x=-a \operatorname{cost}-b \sin t+b t+B
$$

Where $B$ is constant of integration
When $\mathrm{t}=0$ then $\mathrm{x}=0$
$\Rightarrow \quad \mathrm{B}=\mathrm{a}$
Hence the distance travelled is given by

$$
\begin{aligned}
x & =-a \cos t-b \sin t+b t+a \\
& =a(1-\cos t)+b(t-\sin t)
\end{aligned}
$$

(iii)

Given that

$$
\begin{aligned}
& a=-n^{2} x \\
\Rightarrow \quad & v \frac{d v}{d x}=-n^{2} x \quad \because a=v \frac{d v}{d x} \\
\Rightarrow \quad & v d v=-n^{2} x d x
\end{aligned}
$$

On integrating, we get

$$
\frac{v^{2}}{2}=-n^{2} \frac{x^{2}}{2}+A
$$

Where A is constant of integration.

$$
\begin{array}{ll}
\Rightarrow & \mathrm{v}^{2}=2 \mathrm{~A}-\mathrm{n}^{2} \mathrm{x}^{2} \\
\Rightarrow & \mathrm{v}^{2}=\mathrm{B}-\mathrm{n}^{2} \mathrm{x}^{2} \\
\Rightarrow & \mathrm{v}=\sqrt{\mathrm{B}-\mathrm{n}^{2} \mathrm{x}^{2}}
\end{array}
$$

Which is the velocity of the particle.

$$
\begin{aligned}
& \Rightarrow \quad \frac{\mathrm{dx}}{\mathrm{dt}}=\sqrt{\mathrm{B}-\mathrm{n}^{2} \mathrm{x}^{2}} \\
& \Rightarrow \quad \frac{\mathrm{dx}}{\sqrt{\mathrm{~B}-\mathrm{n}^{2} \mathrm{x}^{2}}}=\mathrm{dt}=\frac{\mathrm{dx}}{\mathrm{dt}}
\end{aligned}
$$

On integrating again, we get

$$
\frac{1}{\mathrm{n}} \sin ^{-1}\left(\frac{\mathrm{nx}}{\sqrt{\mathrm{~B}}}\right)=\mathrm{t}+\mathrm{B}
$$

Where B is constant of integration.

$$
\begin{aligned}
& \frac{1}{\mathrm{n}} \sin ^{-1}\left(\frac{\mathrm{nx}}{\sqrt{\mathrm{~B}}}\right)=\mathrm{t}+\mathrm{B} \\
\Rightarrow \quad & \sin ^{-1}\left(\frac{\mathrm{nx}}{\sqrt{\mathrm{~B}}}\right)=\mathrm{nt}+\mathrm{nB} \\
\Rightarrow \quad & \sin ^{-1}\left(\frac{\mathrm{nx}}{\sqrt{\mathrm{~B}}}\right)=\mathrm{nt}+\mathrm{C} \\
\Rightarrow \quad & \mathrm{x}=\frac{\sqrt{\mathrm{B}}}{\mathrm{n}} \sin (\mathrm{nt}+\mathrm{C})
\end{aligned}
$$

## \& QUESTION 4

A particle moves in a straight line with an acceleration $\mathrm{kv}^{3}$. If its initial velocity is $u$, then find the velocity and the time spend when the particle has travelled distance x .

## SOLUTION

Given that

$$
\begin{aligned}
& \mathrm{a}=\mathrm{kv}{ }^{3} \\
\Rightarrow \quad & \mathrm{v} \frac{\mathrm{dv}}{\mathrm{dx}}=k v^{3} \quad \because \mathrm{a}=\mathrm{v} \frac{\mathrm{dv}}{\mathrm{dx}} \\
\Rightarrow \quad & \mathrm{v}^{-2} \mathrm{dv}=\mathrm{kdx}
\end{aligned}
$$

On integrating, we get

$$
-\mathrm{v}^{-1}=\mathrm{kx}+\mathrm{A}
$$

$\qquad$
Where A is constant of integration.
Initially $\mathrm{v}=\mathrm{u}, \mathrm{x}=0$ and $\mathrm{t}=0$

$$
\Rightarrow \quad \mathrm{A}=-\mathrm{u}^{-1}
$$

Using value of A in (i), we get

$$
\begin{aligned}
& -\mathrm{v}^{-1}=\mathrm{kx}-\mathrm{u}^{-1} \\
\Rightarrow \quad & \frac{1}{\mathrm{v}}=\frac{1}{\mathrm{u}}-\mathrm{kx}=\frac{1-\mathrm{kxu}}{\mathrm{u}} \\
\Rightarrow \quad & \mathrm{v}=\frac{\mathrm{u}}{1-\mathrm{kux}}
\end{aligned}
$$

Which is the velocity of the particle.

$$
\Rightarrow \quad \frac{\mathrm{dx}}{\mathrm{dt}}=\frac{\mathrm{u}}{1-\mathrm{kxu}} \quad \because \mathrm{v}=\frac{\mathrm{dx}}{\mathrm{dt}}
$$

$\Rightarrow \quad(1-\mathrm{kxu}) \mathrm{dx}=\mathrm{udt}$
On integrating again, we get

$$
\begin{equation*}
x-k u \frac{x^{2}}{2}=u t+B \tag{ii}
\end{equation*}
$$

Where $B$ is constant of integration.
Initially, $\mathrm{v}=\mathrm{u}, \mathrm{x}=0$ and $\mathrm{t}=0$

$$
\Rightarrow \quad B=0
$$

Using value of $B$ in (ii), we get

$$
\begin{aligned}
& \mathrm{x}-\mathrm{ku} \frac{\mathrm{x}^{2}}{2}=\mathrm{ut} \\
\Rightarrow & \mathrm{ut}=\frac{\mathrm{x}}{2}(2-\mathrm{kux}) \\
\Rightarrow & \mathrm{t}=\frac{\mathrm{x}}{2 \mathrm{u}}(2-\mathrm{kux})
\end{aligned}
$$

Which is required time spend when the particle has travelled a distance x .

## * QUESTION 5

A particle moving in a straight line starts with a velocity $u$ and has acceleration $v^{3}$, where $v$ is the velocity of the particle at time $t$. Find the velocity and the time as functions of the distance travelled by the particle

## SOLUTION

Given that

$$
\begin{aligned}
& a=v^{3} \\
\Rightarrow \quad & v \frac{d v}{d x}=v^{3} \quad \because a=v \frac{d v}{d x} \\
\Rightarrow \quad & v^{-2} d v=d x
\end{aligned}
$$

On integrating, we get

$$
\begin{equation*}
-\mathrm{v}^{-1}=\mathrm{x}+\mathrm{A} \tag{i}
\end{equation*}
$$

Where A is constant of integration.
Initially $\mathrm{v}=\mathrm{u}, \mathrm{x}=0$ and $\mathrm{t}=0$

$$
\Rightarrow \quad \mathrm{A}=-\mathrm{u}^{-1}
$$

Using value of A in (i), we get

$$
\begin{aligned}
& -\mathrm{v}^{-1}=\mathrm{x}-\mathrm{u}^{-1} \\
\Rightarrow \quad & \frac{1}{\mathrm{v}}=\frac{1}{\mathrm{u}}-\mathrm{x}=\frac{1-\mathrm{xu}}{\mathrm{u}}
\end{aligned}
$$

$\Rightarrow \quad \mathrm{v}=\frac{\mathrm{u}}{1-\mathrm{ux}}$
Which is the velocity of the particle.

$$
\begin{array}{ll}
\Rightarrow & \frac{\mathrm{dx}}{\mathrm{dt}}=\frac{\mathrm{u}}{1-\mathrm{xu}} \\
\Rightarrow & (1-\mathrm{xu}) \mathrm{dx}=\mathrm{udt}
\end{array}
$$

On integrating again, we get

$$
\begin{equation*}
x-u \frac{x^{2}}{2}=u t+B \tag{ii}
\end{equation*}
$$

Where B is constant of integration.
Initially, $\mathrm{v}=\mathrm{u}, \mathrm{x}=0$ and $\mathrm{t}=0$
$\Rightarrow \quad \mathrm{B}=0$
Using value of $B$ in (ii), we get

$$
\begin{aligned}
& \mathrm{x}-\mathrm{u} \frac{\mathrm{x}^{2}}{2}=\mathrm{ut} \\
\Rightarrow & \mathrm{ut}=\frac{\mathrm{x}}{2}(2-\mathrm{ux}) \\
\Rightarrow & \mathrm{t}=\frac{\mathrm{x}}{2 \mathrm{u}}(2-\mathrm{ux})
\end{aligned}
$$

## * QUESTION 6

A particle starts with a velocity $u$ and moves in a straight line. If it suffers a retardation equal to the square of the velocity. Find the distance travelled by the particle in a time $t$.

## SOLUTION

Given that
Retardation $=\mathrm{v}^{2}$
$\Rightarrow \quad a=-x^{2}$
$\Rightarrow \quad v \frac{d v}{d x}=-v^{2} \quad \because a=v \frac{d v}{d x}$
$\Rightarrow \quad \frac{\mathrm{dv}}{\mathrm{v}}=-\mathrm{dx}$
On integrating, we get

$$
\begin{equation*}
\ln v=-\mathrm{x}+\mathrm{A} \tag{i}
\end{equation*}
$$

Where A is constant of integration.
Initially $\mathrm{v}=\mathrm{u}, \mathrm{x}=0$ and $\mathrm{t}=0$
$\Rightarrow \quad \mathrm{A}=\ln u$

Using value of A in (i), we get

$$
\begin{array}{ll} 
& \ln v=-\mathrm{x}+\ln \mathrm{u} \\
\Rightarrow \quad & \mathrm{x}=\ln \mathrm{u}-\ln \mathrm{v} \\
\Rightarrow \quad & \mathrm{x}=\ln \left(\frac{\mathrm{u}}{\mathrm{v}}\right) \\
\Rightarrow \quad & \mathrm{e}^{\mathrm{x}}=\frac{\mathrm{u}}{\mathrm{v}} \\
\Rightarrow \quad & \mathrm{v}=\frac{\mathrm{u}}{\mathrm{e}^{\mathrm{x}}}
\end{array}
$$

Which is the velocity of the particle.

$$
\begin{array}{ll}
\Rightarrow & \frac{\mathrm{dx}}{\mathrm{dt}}=\frac{\mathrm{u}}{\mathrm{e}^{\mathrm{x}}}
\end{array} \quad \because \mathrm{v}=\frac{\mathrm{dx}}{\mathrm{dt}}
$$

On integrating again, we get

$$
\begin{aligned}
& \mathrm{e}^{\mathrm{x}} \\
& =\mathrm{ut}+\mathrm{B}
\end{aligned}
$$

Where B is constant of integration.
Initially, $\mathrm{v}=\mathrm{u}, \mathrm{x}=0$ and $\mathrm{t}=0$
$\Rightarrow \quad B=1$
Using value of $B$ in (ii), we get

$$
\mathrm{e}^{\mathrm{x}}=\mathrm{ut}+1 \quad \Rightarrow \quad \mathrm{x}=\ln (1+\mathrm{ut})
$$

## * QUESTION 7

Discuss the motion of a particle moving in a straight line with an acceleration $\mathrm{x}^{3}$ where x is the distance of the particle from a fixed point $O$ on the line, if it starts at $t=0$ from a point $\mathrm{x}=\mathrm{c}$ with a velocity $\mathrm{c}^{2} / \sqrt{2}$

## SOLUTION

Given that

$$
\begin{aligned}
& a=x^{3} \\
\Rightarrow \quad & v \frac{d v}{d x}=x^{3} \quad \because a=v \frac{d v}{d x} \\
\Rightarrow \quad & v d v=x^{3} d x
\end{aligned}
$$

On integrating, we get

$$
\begin{equation*}
\frac{\mathrm{v}^{2}}{2}=\frac{\mathrm{x}^{4}}{4}+\mathrm{A} \tag{i}
\end{equation*}
$$

Where A is constant of integration.
Initially, $\mathrm{t}=0, \mathrm{x}=\mathrm{c}$ and $\mathrm{v}=c^{2} / \sqrt{2}$
$\Rightarrow \quad \mathrm{A}=0$
Using value of A in (i), we get

$$
\begin{aligned}
& \frac{\mathrm{v}^{2}}{2}=\frac{\mathrm{x}^{4}}{4} \\
\Rightarrow & \mathrm{v}^{2}=\frac{\mathrm{x}^{4}}{2} \\
\Rightarrow & \mathrm{v}=\frac{\mathrm{x}^{2}}{\sqrt{2}}
\end{aligned}
$$

Which is the velocity of the particle.

$$
\begin{array}{ll}
\Rightarrow & \frac{\mathrm{dx}}{\mathrm{dt}}=\frac{\mathrm{x}^{2}}{\sqrt{2}} \\
\Rightarrow & \frac{\mathrm{dx}}{\mathrm{x}^{2}}=\frac{\mathrm{dt}}{\sqrt{2}} \\
\Rightarrow & \mathrm{x}^{-2} \mathrm{dx}=\frac{\mathrm{dx}}{\mathrm{dt}} \\
\sqrt{2}
\end{array}
$$

On integrating again, we get

$$
-x^{-1}=\frac{t}{\sqrt{2}}+B
$$

$\qquad$
Where B is constant of integration
Initially, $x=c$ and $t=0$

$$
\Rightarrow \quad B=-\mathrm{c}^{-1}
$$

Using value of $B$ in (iii), we get

$$
\begin{aligned}
& -x^{-1}=\frac{t}{\sqrt{2}}-c^{-1} \\
\Rightarrow & c^{-1}-x^{-1}=\frac{t}{\sqrt{2}} \quad \Rightarrow \quad t=\sqrt{2}\left(c^{-1}-x^{-1}\right) \quad \Rightarrow \quad t=\sqrt{2}\left(\frac{1}{c}-\frac{1}{x}\right)
\end{aligned}
$$

## * QUESTION 8

Discuss the motion of a particle moving in a straight line if it starts from the rest at a distance a from the point O and moves with an acceleration equal to $\mu$ times its distance from O .

## SOLUTION

Let x be the distance of particle from O then

$$
a=\mu x
$$

$$
\begin{array}{ll}
\Rightarrow & v \frac{d v}{d x}=\mu x \\
\Rightarrow & v d v=\mu x d x
\end{array}
$$

On integrating, we get

$$
\begin{equation*}
\frac{\mathrm{v}^{2}}{2}=\frac{\mu \mathrm{x}^{2}}{2}+\mathrm{A} \tag{i}
\end{equation*}
$$

Where A is constant of integration.
Initially, $v=0, x=a$ and $t=0$

$$
\Rightarrow \quad \mathrm{A}=-\frac{\mu \mathrm{a}^{2}}{2}
$$

Using value of A in (i), we get

$$
\begin{array}{rlrl} 
& & \frac{\mathrm{v}^{2}}{2} & =\frac{\mu \mathrm{x}^{2}}{2}-\frac{\mu \mathrm{a}^{2}}{2} \\
\Rightarrow & \mathrm{v}^{2} & =\mu \mathrm{x}^{2}-\mu \mathrm{a}^{2} \\
\Rightarrow & & \mathrm{v} & =\sqrt{\mu\left(\mathrm{x}^{2}-\mathrm{a}^{2}\right)}
\end{array}
$$

Which is the velocity of the particle.

$$
\begin{aligned}
& \Rightarrow \quad \frac{\mathrm{dx}}{\mathrm{dt}}=\sqrt{\mu\left(\mathrm{x}^{2}-\mathrm{a}^{2}\right)} \\
& \Rightarrow \quad \frac{\mathrm{dx}}{\sqrt{\mathrm{x}^{2}-\mathrm{a}^{2}}}=\sqrt{\mu \mathrm{dt}}
\end{aligned}
$$

On integrating again, we get

$$
\begin{equation*}
\cosh ^{-1}\left(\frac{\mathrm{x}}{\mathrm{a}}\right)=\sqrt{\mu} \mathrm{t}+\mathrm{B} \tag{ii}
\end{equation*}
$$

Where B is constant of integration.
Initially, $x=a$ and $t=0$

$$
\Rightarrow \quad \mathrm{B}=\cosh ^{-1} 1=0
$$

Using value of $B$ in (ii), we get

$$
\begin{array}{ll} 
& \cosh ^{-1}\left(\frac{\mathrm{x}}{\mathrm{a}}\right)=\sqrt{\mu} \mathrm{t} \\
\Rightarrow \quad & \mathrm{x}=\mathrm{a} \cosh (\sqrt{\mu} \mathrm{t})
\end{array}
$$

## * QUESTION 9

The acceleration of a particle falling freely under the gravitational pull is equal to $\mathrm{k} / \mathrm{x}^{2}$, where $x$ is the distance of particle from the centre of the earth. Find the velocity of the particle if it is let fall from an altitude $R$, on striking the surface of the earth if the radius of earth is $r$ and the air offers no resistance to motion.

## SOLUTION

Given that

$$
a=-\frac{k}{x^{2}}
$$

Here we measuring distance x from centre O of the earth. The distance and acceleration is in opposite direction. So we take -ive sign. Therefore

$$
\begin{aligned}
& \quad \mathrm{v} \frac{\mathrm{dv}}{\mathrm{dx}}=-\frac{\mathrm{k}}{\mathrm{x}^{2}} \quad \because \mathrm{a}=\mathrm{v} \frac{\mathrm{dv}}{\mathrm{dx}} \\
& \Rightarrow \quad v d v=-\frac{k}{x^{2}} d x
\end{aligned}
$$

On integrating, we get

$$
\begin{equation*}
\frac{\mathrm{v}^{2}}{2}=\frac{\mathrm{k}}{\mathrm{x}}+\mathrm{A} \tag{i}
\end{equation*}
$$

Where A is constant of integration.
When $x=R$ then $v=0$
$\Rightarrow \quad \mathrm{A}=-\frac{\mathrm{k}}{\mathrm{R}}$
Using value of A in (i), we get

$$
\begin{aligned}
& \frac{v^{2}}{2}=\frac{k}{x}-\frac{k}{R} \\
\Rightarrow \quad & \mathrm{v}^{2}=2 \mathrm{k}\left(\frac{1}{\mathrm{x}}-\frac{1}{\mathrm{R}}\right) \\
\Rightarrow \quad & \mathrm{v}=\sqrt{2 \mathrm{k}\left(\frac{1}{\mathrm{x}}-\frac{1}{\mathrm{R}}\right)}
\end{aligned}
$$

## * QUESTION 10

A particle starts from rest with a constant acceleration a. When its velocity acquires a certain value v , it moves uniformly and then its velocity starts decreasing with a constant retardation 2a till it comes to rest. Find the distance travelled by the particle, if the time taken from rest to rest is t .

## SOLUTION

Let $t_{1}, t_{2}$ and $t_{3}$ be the times for acceleration, uniform motion and retardation motion respectively. Then

$$
\begin{equation*}
\mathrm{t}=\mathrm{t}_{1}+\mathrm{t}_{2}+\mathrm{t}_{3} \tag{i}
\end{equation*}
$$

$\qquad$

Now

$$
\begin{aligned}
& \text { acceleration = slope of OA } \\
\Rightarrow & \mathrm{a}=\frac{\mathrm{v}}{\mathrm{t}_{1}} \\
\Rightarrow & \mathrm{t}_{1}=\frac{\mathrm{v}}{\mathrm{a}}
\end{aligned}
$$

Similarly

$$
\text { retardation }=\text { slope of } \mathrm{BC}
$$

$\Rightarrow \quad 2 \mathrm{a}=\frac{\mathrm{v}}{\mathrm{t}_{3}}$
$\Rightarrow \quad \mathrm{t}_{3}=\frac{\mathrm{v}}{2 \mathrm{a}}$
From (i), we have

$$
\begin{aligned}
\mathrm{t}_{2} & =\mathrm{t}-\mathrm{t}_{1}-\mathrm{t}_{3} \\
& =\mathrm{t}-\frac{\mathrm{v}}{\mathrm{a}}-\frac{\mathrm{v}}{2 \mathrm{a}} \\
& =\mathrm{t}-\frac{3 \mathrm{v}}{2 \mathrm{a}}
\end{aligned}
$$

Distance $=$ Area under the velocity-time curve

$$
\begin{aligned}
& =\text { Area of trapezium OABC } \\
& =\frac{1}{2}(\mathrm{OC}+\mathrm{AB})(\mathrm{AD}) \\
& =\frac{1}{2}\left(\mathrm{t}_{1}+\mathrm{t}_{2}+\mathrm{t}_{3}+\mathrm{t}_{2}\right) \mathrm{v} \\
& =\frac{1}{2}\left(\mathrm{t}+\mathrm{t}_{2}\right) \mathrm{v} \\
& =\frac{1}{2}\left(\mathrm{t}+\mathrm{t}-\frac{3 \mathrm{v}}{2 \mathrm{a}}\right) \mathrm{v} \\
& =\frac{1}{2} \mathrm{v}\left(2 \mathrm{t}-\frac{3 \mathrm{v}}{2 \mathrm{a}}\right)
\end{aligned}
$$

## \& QUESTION 11

A particle moving along a straight line starts from rest and is accelerated uniformly until it attains a velocity v . The motion is then retarded and the particle comes to rest after traversing a total distance x . If acceleration is f , find the retardation and the total time taken by the particle from rest to rest.

## SOLUTION

Let $t_{1}$ and $t_{2}$ be the times for acceleration and retardation respectively. Then

$$
\mathrm{t}=\mathrm{t}_{1}+\mathrm{t}_{2}
$$

$\qquad$

Now

$$
\text { acceleration }=\text { slope of } \mathrm{OA}
$$

$$
\begin{array}{ll}
\Rightarrow & \mathrm{f}=\frac{\mathrm{v}}{\mathrm{t}_{1}} \\
\Rightarrow & \mathrm{t}_{1}=\frac{\mathrm{v}}{\mathrm{f}}
\end{array}
$$

Let $g$ be the retardation. Then
retardation $=$ slope of BC
$\Rightarrow \quad \mathrm{g}=\frac{\mathrm{v}}{\mathrm{t}_{2}}$
$\Rightarrow \quad \mathrm{t}_{2}=\frac{\mathrm{v}}{\mathrm{g}}$
Distance $=$ Area under the velocity-time curve

$$
\begin{aligned}
\Rightarrow \quad \mathrm{x} & =\text { Area of } \Delta \mathrm{ABC} \\
& =\frac{1}{2}(\mathrm{OB})(\mathrm{AC}) \\
& =\frac{1}{2}\left(\mathrm{t}_{1}+\mathrm{t}_{2}\right) \mathrm{v} \\
& =\frac{1}{2} \mathrm{tv}
\end{aligned}
$$

$\Rightarrow \quad \mathrm{t}=\frac{2 \mathrm{x}}{\mathrm{v}}$
Thus

$$
\text { Total time }=\frac{2 \mathrm{x}}{\mathrm{v}}
$$

From (ii), we have

$$
\begin{aligned}
\mathrm{x} & =\frac{1}{2}\left(\mathrm{t}_{1}+\mathrm{t}_{2}\right) \mathrm{v} \\
& =\frac{1}{2}\left(\frac{\mathrm{v}}{\mathrm{f}}+\frac{\mathrm{v}}{\mathrm{~g}}\right) \mathrm{v} \\
& =\frac{\mathrm{v}^{2}}{2}\left(\frac{1}{\mathrm{f}}+\frac{1}{\mathrm{~g}}\right) \\
\Rightarrow \quad \frac{2 \mathrm{x}}{\mathrm{v}^{2}} & =\frac{1}{\mathrm{f}}+\frac{1}{\mathrm{~g}} \Rightarrow \frac{1}{\mathrm{~g}}=\frac{2 \mathrm{x}}{\mathrm{v}^{2}}-\frac{1}{\mathrm{f}} \quad \Rightarrow \quad \frac{1}{\mathrm{~g}}=\frac{2 \mathrm{xf}-\mathrm{v}^{2}}{\mathrm{fv}^{2}} \\
\Rightarrow \quad \mathrm{~g} & =\frac{\mathrm{fv}^{2}}{2 \mathrm{xf}-\mathrm{v}^{2}}
\end{aligned}
$$

## \& QUESTION 12

Two particles travel along a straight line. Both start at the same time and are accelerated uniformly at different rates. The motion is such that when a particle attains the maximum velocity v , its motion is retarded uniformly. Two particles come to rest simultaneously at a distance x from the starting point. If the acceleration of the first is a and that of second is $\frac{1}{2} \mathrm{a}$. Find the distance between the point where the two particles attain their maximum velocities.

## sOLUTION

Let both particle attain maximum velocity at $t_{1}$ and $t_{2}$ respectively. Then

## For 1 ${ }^{\text {st }}$ Particle

Acceleration $=$ slope of OA
$\Rightarrow \quad \mathrm{a}=\frac{\mathrm{v}}{\mathrm{t}_{1}} \Rightarrow \mathrm{t}_{1}=\frac{\mathrm{v}}{\mathrm{a}}$

## For $2^{\text {nd }}$ Particle

Acceleration $=$ slope of OB

$$
\Rightarrow \quad \frac{1}{2} \mathrm{a}=\frac{\mathrm{v}}{\mathrm{t}_{2}} \Rightarrow \mathrm{t}_{2}=\frac{2 \mathrm{v}}{\mathrm{a}}
$$

Let $\mathrm{x}_{1}$ and $\mathrm{x}_{2}$ be distances covered by the $1^{\text {st }}$ and $2^{\text {nd }}$ particles to attain velocity v . Then

$$
\begin{aligned}
\mathrm{x}_{1} & =\text { Area of } \triangle \mathrm{OAD} \\
& =\frac{1}{2}(\mathrm{OD})(\mathrm{AD}) \\
& =\frac{1}{2} \mathrm{vt}_{1}=\frac{1}{2} \mathrm{v}\left(\frac{\mathrm{v}}{\mathrm{a}}\right)=\frac{\mathrm{v}^{2}}{2 \mathrm{a}}
\end{aligned}
$$

Similarly

$$
\begin{aligned}
\mathrm{x}_{2} & =\text { Area of } \triangle \mathrm{OBE} \\
& =\frac{1}{2}(\mathrm{OE})(\mathrm{BE}) \\
& =\frac{1}{2} \mathrm{vt}_{2}=\frac{1}{2} \mathrm{v}\left(\frac{2 \mathrm{v}}{\mathrm{a}}\right)=\frac{\mathrm{v}^{2}}{\mathrm{a}}
\end{aligned}
$$

Required Distance $=x_{2}-x_{1}$

$$
=\frac{v^{2}}{a}-\frac{v^{2}}{2 a}=\frac{v^{2}}{2 a}
$$

## * QUESTION 13

Two particles start simultaneously from point O and move in a straight line one with velocity of $45 \mathrm{mile} / \mathrm{h}$ and an acceleration $2 \mathrm{ft} / \mathrm{sec}^{2}$ and other with a velocity of $90 \mathrm{mile} / \mathrm{h}$ and a retardation of $8 \mathrm{ft} / \mathrm{sec}^{2}$. Find the time after which the velocities of particles are same and the distance of O from the point where they meet again.

## SOLUTION

## For ${ }^{\text {st }}$ Particle

Given that

$$
\begin{aligned}
\mathrm{u} & =45 \mathrm{mile} / \mathrm{h} \\
& =\frac{45 \times 1760 \times 30}{60 \times 60}=66 \mathrm{ft} / \mathrm{sec} \\
\mathrm{a} & =2 \mathrm{ft} / \mathrm{sec}^{2}
\end{aligned}
$$

We know that

$$
\begin{align*}
v & =u+a t \\
& =66+2 t \tag{i}
\end{align*}
$$

## For $2^{\text {nd }}$ Particle

Given that

$$
\begin{aligned}
\mathrm{u} & =90 \mathrm{mile} / \mathrm{h} \\
& =\frac{90 \times 1760 \times 30}{60 \times 60}=132 \mathrm{ft} / \mathrm{sec} \\
\mathrm{a} & =-8 \mathrm{ft} / \mathrm{sec}^{2}
\end{aligned}
$$

We know that

$$
\begin{aligned}
\mathrm{v} & =\mathrm{u}+\mathrm{at} \\
& =132-8 \mathrm{t}
\end{aligned}
$$

$\qquad$ (ii)

From (i) and (ii), we get

$$
\begin{aligned}
& 66+2 \mathrm{t}=132-8 \mathrm{t} \\
\Rightarrow \quad & 10 \mathrm{t}=66 \\
\Rightarrow \quad & \mathrm{t}=6.6 \mathrm{sec}
\end{aligned}
$$

So after 6.6 sec velocities of particles will same. Let both particle meet after a distance x .
Then

## For 1 ${ }^{\text {st }}$ Particle

$$
\begin{aligned}
x & =u t+\frac{1}{2} a t^{2} \\
& =66 t+\frac{1}{2}(2) t^{2} \\
& =66 t+t^{2}
\end{aligned}
$$

$\qquad$

## For $2^{\text {nd }}$ Particle

$$
\begin{align*}
\mathrm{x} & =\mathrm{ut}+\frac{1}{2} a \mathrm{t}^{2} \\
& =132 \mathrm{t}+\frac{1}{2}(-8) \mathrm{t}^{2} \\
& =132 \mathrm{t}-4 \mathrm{t}^{2} \tag{iv}
\end{align*}
$$

From (iii) and (iv), we get

$$
\begin{aligned}
& 66 \mathrm{t}+\mathrm{t}^{2}=132 \mathrm{t}-4 \mathrm{t}^{2} \\
\Rightarrow \quad & 5 \mathrm{t}^{2}=66 \mathrm{t} \\
\Rightarrow \quad & \mathrm{t}=13.2
\end{aligned}
$$

Putting value of $t$ in (iii), we get

$$
x=10.4544 \mathrm{ft}
$$

## * VERTICAL MOTION UNDER GRAVITY

For a falling body, the acceleration is constant. It is called acceleration due to gravity and is denoted by "g".

In FPS system value of g is $32 \mathrm{ft} / \mathrm{sec}^{2}$
In CGS system value of g is $981 \mathrm{~cm} / \mathrm{sec}^{2}$
In MKS system value of g is $9.81 \mathrm{~m} / \mathrm{sec}^{2}$
If the body is projected vertically upward then $g=-g$. For a falling body equations of motion are

$$
\begin{aligned}
& \mathrm{v}=\mathrm{u}+\mathrm{gt} \\
& \mathrm{x}=\mathrm{ut}+\frac{1}{2} \mathrm{gt}^{2} \\
& 2 \mathrm{gx}=\mathrm{v}^{2}-\mathrm{u}^{2}
\end{aligned}
$$

Note:
If $\mathrm{ax}^{2}+\mathrm{bx}+\mathrm{c}=0$ be a quadratic equation and $\alpha, \beta$ be the roots of this equation. Then

$$
\alpha+\beta=-\frac{\mathrm{b}}{\mathrm{a}} \text { and } \alpha \beta=\frac{\mathrm{c}}{\mathrm{a}}
$$

## * QUESTION 14

A particle is projected vertically upward at $t=0$ with a velocity $u$, passes a point at a height h at $\mathrm{t}=\mathrm{t}_{1}$ and $\mathrm{t}=\mathrm{t}_{2}$. Show that

$$
t_{1}+t_{2}=\frac{2 u}{g} \text { and } t_{1} t_{2}=\frac{2 h}{g}
$$

## SOLUTION

The distance travelled by the particle in time $t$ is given by

$$
\mathrm{x}=\mathrm{ut}-\frac{1}{2} \mathrm{gt}^{2}
$$

Put $\mathrm{x}=\mathrm{h}$

$$
\begin{aligned}
& \mathrm{h}=\mathrm{ut}-\frac{1}{2} \mathrm{gt}^{2} \\
\Rightarrow \quad & 2 \mathrm{~h}=2 \mathrm{ut}-\mathrm{gt}^{2} \\
\Rightarrow & \mathrm{gt}^{2}-2 \mathrm{ut}+2 \mathrm{~h}=0
\end{aligned}
$$

The time $t_{1}$ and $t_{2}$ when the particle is at a height $h$ from the point of projection, are roots of the quadratic equation

$$
\mathrm{gt}^{2}-2 \mathrm{ut}+2 \mathrm{~h}=0
$$

We know that

$$
\begin{aligned}
& \text { Sum of the roots }=-\frac{\text { coefficient of } t}{\text { coefficient of } t^{2}}, \text { Product of the roots }=\frac{\text { coefficient of } t^{0}}{\text { coefficient of } t^{2}} \\
& \Rightarrow \quad t_{1}+t_{2}=\frac{2 \mathrm{u}}{\mathrm{~g}} \text { and } \mathrm{t}_{1} \mathrm{t}_{2}=\frac{2 \mathrm{~h}}{\mathrm{~g}}
\end{aligned}
$$

## * QUESTION 15

A particle is projected vertically upward with a velocity $\sqrt{2 \mathrm{gh}}$ and another is let fall from a height $h$ at the same time. Find the height of the point where they meet each other.

## sOLUTION

Let both particles meet at point P at height x . Then

## For 1 ${ }^{\text {st }}$ Particle

$$
\begin{equation*}
\mathrm{x}=\mathrm{ut}-\frac{1}{2} \mathrm{gt}^{2} \tag{i}
\end{equation*}
$$

Put $\mathrm{u}=\sqrt{2 \mathrm{gh}}$

$$
x=\sqrt{2 g h} t-\frac{1}{2} g t^{2}
$$

## For $2^{\text {nd }}$ Particle

$$
\mathrm{x}=\mathrm{ut}+\frac{1}{2} \mathrm{gt}^{2}
$$

Put $u=0$ and $x=h-x$

$$
\begin{align*}
& \mathrm{h}-\mathrm{x}=\frac{1}{2} \mathrm{gt}^{2} \\
& \mathrm{x}=\mathrm{h} \frac{1}{2} \mathrm{gt}^{2} \tag{ii}
\end{align*}
$$

From (i) and (ii), we get

$$
\begin{aligned}
& \mathrm{h}-\frac{1}{2} \mathrm{gt}^{2}=\sqrt{2 \mathrm{gh}} \mathrm{t}-\frac{1}{2} \mathrm{gt}^{2} \\
\Rightarrow \quad & \mathrm{~h}=\sqrt{2 \mathrm{gh}} \mathrm{t} \quad \Rightarrow \quad \mathrm{t}=\frac{\mathrm{h}}{\sqrt{2 \mathrm{gh}}}
\end{aligned}
$$

Using value of $t$ in (i), we get

$$
\mathrm{x}=\sqrt{2 \mathrm{gh}} \frac{\mathrm{~h}}{\sqrt{2 \mathrm{gh}}}-\frac{1}{2} \mathrm{~g}\left(\frac{\mathrm{~h}}{\sqrt{2 \mathrm{gh}}}\right)^{2}=\mathrm{h}-\frac{1}{2} \mathrm{~g}\left(\frac{\mathrm{~h}^{2}}{2 \mathrm{gh}}\right)=\mathrm{h}-\frac{\mathrm{h}}{4}=\frac{3 \mathrm{~h}}{4}
$$

## * QUESTION 16

A particle is projected vertically upwards. After a time $t$, another particle is sent up from the same point with the same velocity and meets the first at height $h$ during the downward flight of the first. Find the velocity of the projection.

## SOLUTION

Let $u$ be the velocity of projection and $v$ be the velocity at height $h$. Then

$$
\begin{align*}
& \mathrm{v}^{2}-\mathrm{u}^{2}=-2 \mathrm{gh} \\
\Rightarrow \quad & \mathrm{v}^{2}=\mathrm{u}^{2}-2 \mathrm{gh} \\
\Rightarrow \quad & \mathrm{v}=\sqrt{\mathrm{u}^{2}-2 \mathrm{gh}} \tag{i}
\end{align*}
$$

Since time taken by $1^{\text {st }}$ particle from height h to the maximum point and back to height h is t therefore time taken from the height $h$ to the heights point is $t / 2$. Velocity at the highest point is zero and at the height $h$ the velocity is $v$.
We know that

$$
\mathrm{v}=\mathrm{u}-\mathrm{gt}
$$

Since the velocity at the highest point is zero and at the height $h$ the velocity is v . therefore

$$
\begin{array}{ll}
\text { Put } & v=0, u=v \text { and } t=t / 2 \\
& 0=v-\frac{g t}{2} \\
\Rightarrow \quad & v=\frac{g t}{2} \tag{ii}
\end{array}
$$

$\qquad$
From (i) and (ii), we get

$$
\begin{aligned}
& \frac{\mathrm{gt}}{2}=\sqrt{\mathrm{u}^{2}-2 \mathrm{gh}} \\
\Rightarrow & \frac{\mathrm{~g}^{2} \mathrm{t}^{2}}{4}=\mathrm{u}^{2}-2 \mathrm{gh} \quad \Rightarrow \quad \mathrm{~g}^{2} \mathrm{t}^{2}=4 \mathrm{u}^{2}-8 \mathrm{gh} \\
\Rightarrow & 4 \mathrm{u}^{2}=\mathrm{g}^{2} \mathrm{t}^{2}+8 \mathrm{gh} \quad \Rightarrow \quad 2 \mathrm{u}=\sqrt{\mathrm{g}^{2} \mathrm{t}^{2}+8 \mathrm{gh}} \quad \Rightarrow \quad \mathrm{u}=\frac{\sqrt{\mathrm{g}^{2} \mathrm{t}^{2}+8 \mathrm{gh}}}{2}
\end{aligned}
$$

## * QUESTION 17

A gunner detects a plane at $\mathrm{t}=0$ approaching him with a velocity v , the horizontal and the vertical distances of the plane being $h$ and $k$ respectively. His gun can fire a shell vertically upwards with an initial velocity $u$. Find the time when he should fire the gun and the condition on $u$ so that he may be able to hit the plane if it continuous its flight in the same horizontal line.

## SOLUTION

Let G be a gun and A be the position of plane at $\mathrm{t}=0$. Let gun hits the plane at point B and $A B=h$. Let time taken by plane from $A$ to $B$ is $t_{1}$. Then

$$
\mathrm{t}_{1}=\frac{\text { Distance }}{\text { Velocity }}=\frac{\mathrm{h}}{\mathrm{v}}
$$

Let $t_{2}$. be time taken by shell to reach at point B.
We know that

$$
\mathrm{x}=\mathrm{ut}-\frac{1}{2} \mathrm{gt}^{2}
$$

Putting $\mathrm{x}=\mathrm{k}$ and $\mathrm{t}=\mathrm{t}_{2}$, we get

$$
\begin{array}{ll} 
& \mathrm{k}=\mathrm{ut}_{2}-\frac{1}{2} \mathrm{gt}_{2}{ }^{2} \\
\Rightarrow \quad & 2 \mathrm{k}=2 \mathrm{ut}_{2}-\mathrm{gt}_{2}{ }^{2} \\
\Rightarrow & \mathrm{gt}_{2}{ }^{2}-2 \mathrm{ut}_{2}+2 \mathrm{k}=0 \\
\Rightarrow & \mathrm{t}_{2}=\frac{2 \mathrm{u} \pm \sqrt{4 \mathrm{u}^{2}-8 \mathrm{gk}}}{2 \mathrm{~g}}=\frac{\mathrm{u} \pm \sqrt{\mathrm{u}^{2}-2 \mathrm{gk}}}{\mathrm{~g}}
\end{array}
$$

Let T be the time after which gun should be fired. Then

$$
\begin{aligned}
\mathrm{T} & =\mathrm{t}_{1}-\mathrm{t}_{2} \\
& =\frac{\mathrm{h}}{\mathrm{v}}-\frac{\mathrm{u} \pm \sqrt{\mathrm{u}^{2}-2 \mathrm{gk}}}{\mathrm{~g}}
\end{aligned}
$$

For a shell to reach at $B$, the maximum velocity at $B$ is zero.
Since

$$
\mathrm{v}^{2}-\mathrm{u}^{2}=2 \mathrm{ax}
$$

Putting $v=0, a=-g$ and $x=k$, we get
$-u^{2}=-2 \mathrm{gk} \Rightarrow \mathrm{u}^{2}=2 \mathrm{gk}$
Which gives the least value of $u$. Hence $u^{2}>2 g k$

## * QUESTION 18

Two particles are projected simultaneously in the vertically upward direction with velocities $\sqrt{2 \mathrm{gh}}$ and $\sqrt{2 \mathrm{gk}}(\mathrm{k}>\mathrm{h})$. After time t , when the two particles are still in flight, another particle is projected upwards with velocity $u$. Fin the condition so that the third particle may meet the first two during their upward flight.

## SOLUTION

For $1^{\text {st }}$ particle

$$
\mathrm{v}^{2}-\mathrm{u}^{2}=2 \mathrm{ax}
$$

For maximum height put $\mathrm{v}=0, \mathrm{a}=-\mathrm{g}$ and $\mathrm{u}=\sqrt{2 \mathrm{gh}}$

$$
\begin{aligned}
& 2 \mathrm{gh}=2 \mathrm{gx} \\
\Rightarrow \quad & \mathrm{a}=\mathrm{h}
\end{aligned}
$$

Thus maximum height attained by $1^{\text {st }}$ particle is $h$. Similarly maximum height attained by $2^{\text {nd }}$ particle is k .
Let $t_{1}$ be time take by the $1^{\text {st }}$ particle to attain the maximum height $h$ then

$$
\mathrm{v}=\mathrm{u}+\mathrm{at}
$$

Put $\mathrm{v}=0, \mathrm{u}=\sqrt{2 \mathrm{gh}}, \mathrm{a}=-\mathrm{g}$ and $\mathrm{t}=\mathrm{t}_{1}$

$$
0=\sqrt{2 \mathrm{gh}}-\mathrm{gt}_{1}
$$

$\Rightarrow \quad \mathrm{t}_{1}=\frac{\sqrt{2 \mathrm{gh}}}{\mathrm{g}}$
$\Rightarrow \quad \mathrm{t}_{1}=\sqrt{\frac{2 \mathrm{~h}}{\mathrm{~g}}}$
Similarly time $t_{2}$ taken by the $2^{\text {nd }}$ particle to attain the maximum height k is

$$
\mathrm{t}_{2}=\sqrt{\frac{2 \mathrm{k}}{\mathrm{~g}}}
$$

Since $k>h$ therefore $t_{2}>t_{1}$
Thus the $1^{\text {st }}$ particle reach the maximum height earlier then $2^{\text {nd }}$.
If the $3^{\text {rd }}$ particle is projected after time $t$ then $t$ must be less than $t_{1}$ in order to meet the $1^{\text {st }}$ two particles during their upward flight. i.e. $\mathrm{t}<\mathrm{t}_{1}$
or $\quad \mathrm{t}<\sqrt{\frac{2 \mathrm{~h}}{\mathrm{~g}}}$
Now time left with $3^{\text {rd }}$ particle is

$$
\sqrt{\frac{2 h}{g}}{ }^{2}
$$

and during this time it has to meet both the particles. i.e. It may have to cover a distance k . Since

$$
\mathrm{x}=\mathrm{ut}-\frac{1}{2} \mathrm{gt}^{2}
$$

When $x=k$, time $=\sqrt{\frac{2 h}{g}}-t$ Then

$$
\mathrm{k}=\mathrm{u}\left(\sqrt{\frac{2 \mathrm{~h}}{\mathrm{~g}}}-\mathrm{t}\right)-\frac{1}{2} \mathrm{~g}\left(\sqrt{\frac{2 \mathrm{~h}}{\mathrm{~g}}}-\mathrm{t}\right)^{2}
$$

$$
\begin{aligned}
& \Rightarrow \quad \mathrm{k}+\frac{1}{2} \mathrm{~g}\left(\sqrt{\frac{2 \mathrm{~h}}{\mathrm{~g}}}-\mathrm{t}\right)^{2}=\mathrm{u}\left(\sqrt{\frac{2 \mathrm{~h}}{\mathrm{~g}}}-\mathrm{t}\right) \\
& \Rightarrow \quad \mathrm{u}=\frac{\mathrm{k}}{\sqrt{\frac{2 \mathrm{~h}}{\mathrm{~g}}-\mathrm{t}}}+\frac{1}{2} \mathrm{~g}\left(\sqrt{\frac{2 h}{\mathrm{~g}}}-\mathrm{t}\right) \\
& \Rightarrow \quad \mathrm{u}=\frac{\mathrm{k}}{\sqrt{\frac{2 \mathrm{~h}}{\mathrm{~g}}}-\mathrm{t}}+\frac{1}{2}(\sqrt{2 \mathrm{hg}}-\mathrm{t})
\end{aligned}
$$

Thus the third particle meet the tow $1^{\text {st }}$ particles if

$$
\mathrm{u}>\frac{\mathrm{k}}{\sqrt{\frac{2 \mathrm{~h}}{\mathrm{~g}}-\mathrm{t}}}+\frac{1}{2}(\sqrt{2 \mathrm{hg}}-\mathrm{t})
$$

## \%\%\%\%\%\% End of The Chapter \# 5 \%\%\%\%\%\%
